# Methods for Optimizing Interplanetary Trajectories 

Bruce A. Conway<br>Professor<br>Dept. of Aerospace Engineering<br>University of Illinois at Urbana

## Aerospace Engineering

University of Illinois at Urbana-Champaign

## Motivation (1)

- There are several different methods already proposed for NEA mitigation including: (sudden) deflection by collision (sudden) deflection by nuclear explosion
(slow) deflection using gravity tractor
(slow) deflection using Yarkovsky effect
(slow) deflection using surface mass driver
- These different methods can require different types of spacecraft trajectories, e.g. the first requires interception while the others need rendezvous.
- The trajectories in either case may use impulsive (chemical) thrust, or low (electric) thrust, or a combination of the two.
- The trajectories may make use of planetary flybys (gravity assist maneuvers)

## Motivation (2)

-These trajectories are all too challenging to solve analytically - need a numerical solution.
-Unfortunately each combination of possible trajectory elements:
interception/rendezvous
impulsive thrust/ low-thrust/ combination
planetary flybys/ no planetary flybys
may require a different numerical solution approach.
-However one thing that nearly all such solutions will have in common, based on our experience, is that accurate solutions require a two-step process:

Find approximate solution (guess) Refine guess with accurate solver

## Motivation (3)

- So this series of three lectures is intended to (only):
> Show how to formulate the trajectory optimization problem for some of the mitigation strategies
> Describe the numerical solution methods available
> Show what numerical solution approaches have been successful with a number of these possible missions (via examples)
(Note that the first two items alone could easily constitute a year-long graduate-level class.)

## Lecture 1: Methods for Optimizing Interplanetary Trajectories I

The problem: objectives, equations of motion, typical boundary conditions
Methods of solution, indirect vs. direct

Brief Summary of Extant Methods for Trajectory Optimization
1960' s - Hamiltonian methods, primer vector theory
1980' s - Direct transcription (DT), collocation with NLP
2000' s - Evolutionary algorithms (EA) and metaheuristics
Most important distinction: impulsive or low-thrust propulsion - impulsive case is a parameter optimization problem/ L-T case is a continuous optimization problem

Low-thrust case much more challenging. Possible solution strategies:
Hamiltonian (COV) methods
direct transcription (DT)
"shape-based" methods
Sims-Flanagan transcription
The need for an initial guess of the solution and how to obtain one

# Lecture 2: Methods for Optimizing Interplanetary Trajectories II / Application to the Problem of NEA Deflection 

Metaheuristic methods for solution of optimal spacecraft trajectory problems: as initial guess for a more precise method or as solution in own right

Need different approaches for "naturally discrete" problems/ continuous-thrust problems
Examples

Proposed methods of asteroid deflection: collision, nuclear explosion, mass drivers, gravity tractor. Advantages and disadvantages.

The objective: maximizing deflection (easy) vs. maximizing displacement from Earth surface (complicated)

Using the state transition matrix to optimize deflection via collision

Optimizing asteroid deflection via collision using a low-thrust spacecraft

Setting up the problem for solution by a numerical optimization method
Example trajectories and resulting deflections

A related problem: reconnaissance of a potentially dangerous asteroid
Optimizing a reconnaissance/sample return mission to an asteroid using particle swarm optimization

Examples and results

## The Spacecraft Trajectory Optimization Problem

Objective: minimize propellant mass required, minimize flight time, maximize miss distance of NEA at time of closest approach

Equations of Motion: Can be directly based on Newton's $2^{\text {nd }}$ law, e.g.

$$
\dot{\bar{x}}=\bar{f}=\left[\begin{array}{c}
\dot{\bar{r}} \\
\dot{\overline{\mathrm{v}}}
\end{array}\right]=\left[\begin{array}{cc}
\overline{\mathrm{v}} & \\
\overline{\mathrm{~g}}(\mathrm{r})+ & \hat{\mathrm{u}}
\end{array}\right]
$$

or, may be Gauss or Lagrange form of variational eqns. in terms of orbital elements, i.e.

$$
\dot{\bar{x}}=\left[\begin{array}{c}
\dot{a} \\
\dot{e} \\
\dot{i} \\
\cdot \\
\cdot \\
\dot{M} \\
\dot{m}
\end{array}\right]=\bar{f}
$$

## The Spacecraft Trajectory Optimization Problem

Typical boundary conditions: arrive into specified orbit at destination planet (Galileo) perform flyby of destination planet (Voyager) arrive into halo orbit (ISEE-3) land on planetary surface orbit transfer (e.g. LEO to GEO)

University of Illinois at Urbana-Champaign

## Methods of Solution: Indirect vs. Direct

Solutions can be categorized into two basic types: Indirect and Direct

$$
\underline{\text { Indirect }}
$$

Uses the analytical necessary conditions ( $\mathrm{NC} \mathrm{)} \mathrm{of} \mathrm{the} \mathrm{calculus} \mathrm{of} \mathrm{variations} \mathrm{(COV)}$

These are sometimes also referred to as
Hamiltonian methods

A particular application of the COV to space trajectory optimization yields "primer vector" theory

Few analytical solutions possible; must solve the NC using a numerical method

Characterized by having few, 10 's to 100 's, of free parameters (usually initial multipliers)
Direct

Transforms the continuous optimization problem into a discrete parameter optimization (NLP) problem

Many transcription methods extant: direct collocation, Gauss pseudospectral methods, R-K parallel shooting

Very simply incorporates control bounds and boundary conditions (terminal and path constraints)

Typically yields 100 's to 1000 's of free parameters (usually states and controls)

## The Optimal Control Problem

System: $\quad \dot{x}=f(x, u, t), x(0)$ given

$$
[x(T), T]=0, \quad q \text { constraint eqns. }
$$

Problem: Find control $u(\mathrm{t})$ to minimize $\quad J=[x(T), T]+\int_{0}^{T} L[x, u, t] d t$
Calculus of Variations necessary conditions: (Euler-Lagrange equations)

$$
\begin{gathered}
\text { Define Hamiltonian } H=L+{ }^{T} f \text {, then } \\
\left.=-\left(\frac{H}{x}\right)^{T}, \quad(T)=\left[(\bar{x})+{ }^{T}\right]_{x}\right]_{t=T}^{T} \\
\frac{H}{u}=0,
\end{gathered}
$$

either T given, or

$$
\left[\overline{-}+T \frac{T}{t}+\left(\frac{-}{x}+T^{T}\right) f+L\right]_{t=T}=0
$$

## Analytical (COV-Based) Methods

$\dot{x}=\sqrt{2 g y} \cos , x(0)=0$
$\dot{y}=\sqrt{2 g y} \sin , y(0)=y_{0}, y\left(t_{f}\right)=y_{0}$
Define
$H=1+{ }_{x} \sqrt{2 g y} \cos +{ }_{y} \sqrt{2 g y} \sin$

Then, the necessary conditions for an optimal trajectory become:

$$
\begin{aligned}
& x=\frac{H}{x}=0 \\
& y=\frac{H}{y}=\sqrt{\frac{g}{2 y}} x^{\cos } \sqrt{\frac{g}{2 y}} y_{y} \sin
\end{aligned}
$$

with

$$
\begin{aligned}
x\left(t_{f}\right) & =0 \\
y\left(t_{f}\right) & ={ }_{y}, \text { a constant }
\end{aligned}
$$

## Aerospace Engineering

This is a TPBVP with 4 ODE' s . The optimal control is determined directly by the Lagrange multipliers through the optimality condition.
and
$\xrightarrow{H}=0=\sin _{x}+\cos _{y} \quad \frac{y}{x}=\tan$ with $\mathrm{H}\left(t_{f}\right)=0$

## Continuous System with Control Constraints

When there are constraints on the magnitude of the control $u$ the control is determined according to:
$\frac{\mathrm{H}}{u}=0 \quad$ if the resulting $u$ satisfies the constraints,
or, $u$ is chosen to minimize the instantaneous value of the Hamiltonian H (Pontryagin minimum principle).

In both cases, the optimality condition is a function of the instantaneous states, the instantaneous values of the Lagrange multipliers (costates), or both.

## Lagrange and Me

University of Illinois at Urbana-Champaign

## Generic Spacecraft in Inverse-Square Gravitational Field

- The system differential equations become

$$
\begin{aligned}
& \frac{d r}{d t}=\mathrm{v}_{\mathrm{r}} \\
& \frac{d \theta}{d t}=\mathrm{v}_{\theta} / \mathrm{r} \\
& \frac{d v_{r}}{d t}=\mathrm{v}_{\theta}{ }^{2} / \mathrm{r}+\mathrm{g}(\mathrm{r})+\mathrm{sa} \sin \beta \\
& \frac{d v_{\theta}}{d t}=-\mathrm{v}_{\mathrm{r}} \mathrm{v}_{\theta} / \mathrm{r}+\mathrm{s} \mathrm{a} \cos \beta \\
& \frac{d a}{d t}=\mathrm{sa}^{2} / \mathrm{c} .
\end{aligned}
$$

or $\bar{x}=\left[r, \quad, v_{r}, v, a\right]^{T}, u=$
where: s is the throttling parameter, $0 \quad \mathrm{~s} \quad 1$
gravitational force function $g(r)=-1 / r^{2}$

## Necessary Conditions - Lagrange Multiplier DE's

In this coordinate system the multiplier (costate) differential equations become:

$$
\frac{d}{d t}=F(x, u)^{T}, \text { with } F(x, u)=\frac{f}{d x}
$$

where $=\left[{ }_{r}, \quad, \quad v r, v,{ }_{a}\right]^{\mathrm{T}}, \mathrm{x}=\left[\mathrm{r}, v_{r}, v, a\right]^{T}, u=$, and the F matrix is:

$$
F=\left[\begin{array}{ccccc}
0 & 0 & 1 & 0 & 0 \\
v / r^{2} & 0 & 0 & 1 / r & 0 \\
v^{2} / r^{2}+2 / r^{3} & 0 & 0 & 2 v / r & s \sin \\
v_{r} v / r^{2} & 0 & v / r & v_{r} / r & s \cos \\
0 & 0 & 0 & 0 & 2 s a / c
\end{array}\right]
$$

## Aerospace Engineering

University of Illinois at Urbana-Champaign

## Possible Objectives

For the impulsive case the fuel-minimizing trajectory minimizes the sum of the impulses, i.e.

$$
J=\sum_{i=1}^{N}\left|\bar{V}_{i}\right|
$$

For the continuous thrust case the fuel-minimizing trajectory minimizes:

$$
J={ }_{0}^{t_{f}} s a d t={ }_{0}^{t_{f}} s \frac{T}{m} d t
$$

where T is the thrust provided by the engine and $s$ is the throttling parameter $\left(\begin{array}{lll}0 & s & 1\end{array}\right)$

For the minimum-time case the objective becomes

$$
\mathrm{J}=\left[x\left(t_{f}\right), t_{f}\right]=t_{f} \text { or } J=\int_{t_{0}}^{t_{f}} L d t=\int_{t_{0}}^{t_{f}} 1 d t
$$

## Necessary Conditions - Optimal Control

The Hamiltonian can be written in a more compact form by
defining: $\quad \overline{\mathrm{r}}=\left[\begin{array}{l}\mathrm{r}\end{array}\right], \overline{\mathrm{v}}=\left[\begin{array}{l}\mathrm{v}_{\mathrm{r}} \\ \mathrm{v}\end{array}\right], \underset{r}{-}=\left[\begin{array}{c}\mathrm{r} \\ \end{array}\right], \underset{v}{-}=\left[\begin{array}{c}\mathrm{vr} \\ \mathrm{v}\end{array}\right], \bar{u}=\left[\begin{array}{l}\cos \\ \sin \end{array}\right]$

Consider the minimum-fuel case with $L=\mathrm{s}$, then
$H=s+{ }_{r}^{-T} \overline{\mathrm{v}}+{ }_{v}^{-T}[\bar{g}(\bar{r})+s a \bar{u}]+{ }_{a} s a^{2} / c$
or, $\quad H=s\left(1+a^{-T} \bar{v} \bar{u}+{ }_{a} a^{2} / c\right)+{ }_{r}^{-T} \overline{\mathrm{v}}+{ }_{v}{ }_{v}^{T} \bar{g}(\bar{r})$
to minimize $H$ over all possible $\bar{u}$, one chooses
$\bar{u}=-^{-} v$ "primer vector theory" (1960's) (which is equivalent to tan $=\frac{\mathrm{vr}}{\mathrm{v}}$ )

## Necessary Conditions-Switching Function

With $\bar{u}={ }^{-}{ }_{v}$, the Hamiltonian becomes:
$H=s\left(1 \quad a_{v}+{ }_{a} a^{2} / c\right)+{ }_{r}{ }_{r} \overline{\mathrm{v}}+{ }_{v}{ }_{v} \bar{g}(\bar{r})$

Let $S=\left(\begin{array}{ll}1 & a_{v}+{ }_{a} a^{2} / c\end{array}\right)$

To minimize H over the throttling parameter $s$ one chooses:
$s=1$ if $\mathrm{S}>0$
$s=0$ if $\mathrm{S}<0$
i.e. $\mathrm{S}=\left(\begin{array}{ll}1 & a_{v}+{ }_{a} a^{2} / c\end{array}\right)$ is the "switching function" for the control.

The optimal control may consist of a sequence of alternating max.
thrust arcs and coast arcs.
The problem is solved if the initial values of the Lagrange multipliers can be determined!

## Example: Optimal (minimum-fuel) Low-Thrust Rendezvous, Solved Using the

 Analytical Necessary Conditions- $\mathrm{r}_{\text {init }}=1, \mathrm{r}_{\text {final }}=3$, target lead angle $4.5 \mathrm{rad}, \mathrm{a}_{0}=0.1, \mathrm{c}=1.5$
- Initial and final orbits are circular
- A TPBVP solver is used to find the required initial values of

## Aerospace Engineering

University of Illinois at Urbana-Champaign

## Analytical (COV-Based) Methods Advantages and Disadvantages

- Advantages

Familiar
A solution provides information, via the primer vector, about how it may be improved, e.g. with a midcourse impulse or coast arc.
No question about optimality (local minimum)
Optimal control determined analytically
Costates represent sensitivity of cost to changes in the states

- Disadvantages

Immediately increases the dimension of the system by 2 x
Can't cope with tabular data, e.g. thrust vs. altitude and temperature
Yields a TPBVP; difficult to solve without good initial states/costates
Changes in terminal conditions or constraints require changes in the system equations
Including path constraints (e.g. dynamic pressure constraints) is problematic

## Direct Transcription (DT) Solutions

Collocation or Pseudospectral methods divide continuous history into segments. States and controls are known only at discrete points. Implicit integration rules, written as nonlinear constraints, enforce satisfaction of the equations of motion.
The optimal control problem is converted into a NLP problem.

## Aerospace Engineering

University of Illinois at Urbana-Champaign

## Direct Transcription (DT) Solutions

In the collocation method we assume that within each segment the state is described by a polynomial in time, e.g. $x=c+c_{1} s+c_{2} s^{2}+c_{3} s^{3}$
Choose "collocation" point at the center of the segment. Then,

$$
\begin{aligned}
\mathrm{x}\left(\mathrm{t}_{\mathrm{c}}\right) & =\mathrm{x}(\mathrm{~s}=1 / 2)=\mathrm{c}_{0}+\frac{\mathrm{c}_{1}}{2}+\frac{\mathrm{c}_{2}}{4}+\frac{\mathrm{c}_{3}}{8} \\
= & \frac{\mathrm{x}_{\mathrm{i}}+\mathrm{x}_{\mathrm{i}+1}}{2}+\frac{\mathrm{t}_{\mathrm{i}}\left[\mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)-\mathrm{f}\left(\mathrm{t}_{\mathrm{i}+1}\right)\right]}{8} \\
\dot{\mathrm{x}}\left(\mathrm{t}_{\mathrm{c}}\right) & =\dot{\mathrm{x}}(\mathrm{~s}=1 / 2)=\left[\mathrm{c}_{1}+\mathrm{c}_{2}+\frac{3 \mathrm{c}_{3}}{4}\right] \frac{1}{\mathrm{t}_{\mathrm{i}}} \\
= & \frac{-3\left[\mathrm{x}_{\mathrm{i}}-\mathrm{x}_{\mathrm{i}+1}\right]}{2 \mathrm{t}_{\mathrm{i}}}-\frac{\left[\mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)+\mathrm{f}\left(\mathrm{t}_{\mathrm{i}+1}\right)\right]}{4}
\end{aligned}
$$

Forcing $\dot{x}\left(t_{c}\right)$, the slope of the polynomial, to equal the function, evaluated at the center point, $f\left(\mathrm{t}_{\mathrm{c}}, \mathrm{x}\left(\mathrm{t}_{\mathrm{c}}\right)\right)$, yields

$$
\mathrm{x}_{\mathrm{i}+1}-\mathrm{x}_{\mathrm{i}}-\frac{\mathrm{t}_{\mathrm{i}}}{6}\left[\mathrm{f}\left(\mathrm{t}_{\mathrm{i}}\right)+4 \mathrm{f}\left(\mathrm{t}_{\mathrm{c}}\right)+\mathrm{f}\left(\mathrm{t}_{\mathrm{i}+1}\right)\right]=0
$$

which is Simpson's rule!

## Direct Transcription (DT) Solutions

Another DT scheme is Runge-Kutta parallel-shooting. R-K parallel shooting uses explicit numerical integration in creating the nonlinear constraints.

$$
\begin{aligned}
& y_{i 1}^{1}=x_{i 1}+\frac{1}{2 p} h f\left(x_{i 1}, u_{i 1}\right) \\
& y_{i 1}^{2}=x_{i 1}+\frac{1}{2 p} h f\left(y_{i 1}^{1}, \quad, i 1\right) \\
& y_{i 1}^{3}=x_{i 1}+\frac{1}{p} h f\left(y_{i 1}^{2}, \quad, i 1\right)
\end{aligned}
$$

$$
\left.\left.\begin{array}{rl}
y_{i 1}^{4}=x_{i 1}+ & \frac{1}{6 p} h\left[f\left(x_{i 1}, u_{i 1}\right)+2 f\left(y_{i 1}^{1},{ }_{i 1}\right)+2 f\left(y_{i 1}^{2},{ }_{i 1}\right)+f\left(y_{i 1}^{3},\right.\right. \\
i 2
\end{array}\right)\right] ~\left\{\begin{array}{l}
\quad=y_{i 3}^{4} \quad x_{i}=0
\end{array}\right.
$$

## Direct Transcription (DT) Solutions Conversion into NLP problem

Collect all independent variables into a single vector $\quad \mathbf{P}^{\mathrm{T}}=\left\langle\mathbf{Z}^{\mathrm{T}}, \mathbf{E}^{\mathrm{T}}\right]$
where $\mathbf{Z}^{\mathrm{T}}=\left(\mathbf{x}_{1}^{\mathrm{T}}, \mathbf{u}_{1}^{\mathrm{T}}, \mathbf{x}_{2}^{\mathrm{T}}, \mathbf{u}_{2}^{\mathrm{T}}, \ldots, \mathbf{x}_{\mathrm{N}+1}^{\mathrm{T}}, \mathbf{u}_{\mathrm{N}+1}^{\mathrm{T}}\right)$

$$
\mathbf{E}^{\mathbf{T}}=\left(\mathrm{E}_{1}, \mathrm{E}_{2}, \ldots, \quad \mathrm{E}_{\mathrm{L}}\right)
$$

Problem is then of form: minimize
(P) subject to constraints

$$
\left.\mathbf{b}_{\mathrm{L}} \quad \left\lvert\, \begin{array}{c}
\mathbf{P} \\
\mathrm{A} \mathbf{P} \\
\mathbf{C}(\mathbf{P})
\end{array}\right.\right\} \quad \mathbf{b}_{\mathrm{U}}
$$

where $A \mathbf{P}$ contains all of the linear constraints, $\mathbf{C}(\mathbf{P})$ is a vector of all of the nonlinear constraints.

There will be $(\mathrm{N}+1)$ (number of state variables + number of control variables) parameters in the vector $\mathbf{Z}$; usually only a small number of parameters, such as switching times for motor operation, in the event vector $\mathbf{E}$.

## Direct Transcription (DT) Solutions Advantages and Disadvantages

- Advantages

Straightforward to code
Don' t need to know optimal control theory; don' t need possibly difficult analytical differentiation
Generally robust; tolerant of poor initial guess
Control constraints are included trivially
Constraints such as dynamic pressure constraints, which are problematic for COV methods, are simply included
Changes in terminal conditions or constraints easily made

- Disadvantages

States and controls known only at discrete points
No guarantee of optimality
Need a sufficiently good initial guess - can sometimes use intuition or experience;
for challenging problem probably need approximate numerical solution (or homotopy)
Likely to converge to a minimum in the neighborhood of the initial guess
The solution provides no information about possible improvement; it is the
best solution for the given structure.

University of Illinois at Urbana-Champaign

## Example: Optimal Low-Thrust Transfer from LEO to Periodic Orbit About $\mathrm{L}_{1}$, Solved Using Direct Transcription

The solution uses the collocation method with NLP

Step 1: The system DE's are numerically integrated assuming thrust is always directed along the velocity vector. The integration ends when the $S / C$ is near the periodic orbit. This provides the initial guess.

Step 2: The numerically integrated trajectory is used as an initial guess for the NLP solver. The optimizer is required to reach only a specific point on the periodic orbit, i.e. to minimize $=\left(\begin{array}{ll}x_{\mathrm{f}} & x_{s}\end{array}\right)^{2}+\left(\begin{array}{ll}y_{\mathrm{f}} & y_{s}\end{array}\right)^{2}$

Step 3: The previous trajectory is used as an initial guess for the NLP solver. The optimizer is required to achieve a specific velocity on the periodic orbit i.e. by minimizing $=\left(\begin{array}{ll}v_{x_{\mathrm{f}}} & v_{x_{s}}\end{array}\right)^{2}+\left(\begin{array}{ll}v_{y_{\mathrm{f}}} & v_{y_{s}}\end{array}\right)^{2}$ but with final position constrained to the same point $\left(x_{s}, y_{s}\right)$.

Step 4: The previous solution is used as an initial guess for the NLP solver. The optimizer is now allowed to move the entry point to any position on the periodic orbit in order to minimize the final time, $t_{f}$, (which simultaneously minimizes fuel consumption.)

## Evolutionary Algorithms (EA's) and Metaheuristics

"Evolutionary computation has as its objective to mimic processes from natural evolution, where the main concept is survival of the fittest: the weak must die." A. Engelbrecht, Computational Intelligence (2007)

Among the best known and most often employed EA's and heuristics are:
Genetic Algorithms (GA) which model genetic evolution
Differential Evolution Algorithms (DE) similar to GA but for continuous-valued problems; also the mutation operator is dependent on the current population

Particle Swarm Algorithms (PSO) which model cooperative behavior of a swarm; e.g. a flock of birds

Ant Colony Algorithms (ACO) model the foraging behavior of ants

## Genetic Algorithm

- The genetic algorithm (GA) is a method for solving an optimization problem starting from a set of completely random candidate solutions and searching for a solution using three principles of biological evolution:
- Tournament selection

| 1 | 2 | 3 | 4 | 3 | 4 | 5 | 6 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 9 | 6 | 7 | 2 | 8 | 1 | 6 |

- Binary crossover

| 0 | 9 | 6 | 4 | 3 | 4 | 1 | 6 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

- Uniform mutation

| 1 | 2 | 3 | 9 | 3 | 4 | 5 | 6 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

- Elitism (retain at least the best $n$ unmodified individuals from the previous generation)
- There are both integer and real forms of the GA

## Particle Swarm Optimization

The Particle Swarm Optimization (PSO) technique mimics the unpredictable motion of bird flocks while searching for food.

The initial population is randomly generated.
At a given iteration each particle is associated with a position vector and a velocity vector.

The formula for velocity update includes three terms with stochastic weights: The inertial component is proportional to the particle velocity in the preceding iteration
The cognitive component is directed toward the best position experienced by the particle
The social component is directed toward the best position yet located by any particle in the swarm.

At the end of the process the best particle is expected to contain the globally optimal values of the unknown parameters in the search space.

## Particle Swarm Optimization

## At the jth iteration, for particles $\mathbf{i}=1, \ldots, \mathbf{N}$

i) For $\mathrm{i}=1, \ldots, \mathrm{~N}$ : evaluate the objective function associated with particle i, $J^{(j)}(i)$
ii) Determine the best position ever visited (i.e. at any generation) by particle i,
iii) Determine the best position ever visited by any particle in the swarm, $Y^{(j)}(i)$
iv) Update the velocity vector for each particle:

$$
w_{k}^{(j+1)}(i)=c_{I} w_{k}^{(j)}(i)+c_{c}\left[\begin{array}{cc}
{ }_{k}^{(j)}(i) & \left.x_{k}^{(j)}(i)\right]+c_{s}\left[Y_{k}^{(j)}(i)\right. \\
\left.x_{k}^{(j)}(i)\right], \quad k=1, \ldots, n
\end{array}\right.
$$

where the inertial, cognitive, and social weights have the following form:

$$
\mathrm{c}_{I}=\frac{1+r_{1}(0,1)}{2}, c_{c}=1.49445 r_{2}(0,1), c_{s}=1.49445 r_{3}(0,1)
$$

v) Update the position vector for each particle*: $x_{k}^{(j+1)}(i)=x_{k}^{(j)}(i)+w_{k}^{(j+1)}(i), \quad k=1, \ldots, n$
vi) Terminate when max number of iterations $N_{I T}$ is reached.

## Aerospace Engineering

University of Illinois at Urbana-Champaign

## Particle Swarm Optimization Incorporating Constraints

- Two ways of dealing with problems with constraints: $g_{j}(\bar{x}) \quad 0, h_{j}(x)=0$

1) Penalty method fitness $(\vec{x})=\left\{\begin{array}{c}f(\vec{x}), \quad \text { if } \vec{x} \in F \\ f(\vec{x})+\operatorname{penalty}(\vec{x}), \text { otherwise }\end{array}\right.$

$$
\operatorname{penalty}(\vec{x})=w_{j=1} \times_{j}(\vec{x}) \quad j(\vec{x})=\begin{array}{lll}
\max \left(0, g_{j}\left(\vec{x}_{i}\right)\right), \text { if } 1 & j \quad q \\
\left|h_{j}(\vec{x})\right| \text {, if } q+1 & j \quad m
\end{array}
$$

2) Multi-objective GA

$$
\begin{aligned}
& \text { fitness }_{1}(\vec{x})=f(\vec{x}) \\
& \text { fitness }_{i+1}(\vec{x})={ }_{i}(\vec{x}) \quad \text { for } \mathrm{i}=1 \text { to } \mathrm{m}
\end{aligned}
$$

- Result is Pareto optimal set of solutions
- Which solution is used for further analysis?

## Aerospace Engineering

## Test Case 1 Solved via Conventional Methods

$$
\begin{aligned}
& \min _{\rho_{1}, \rho_{2}} F(\rho)=\rho_{1}^{2}+\rho_{2}^{2}+\log \left(\rho_{1} \rho_{2}\right) \\
& c(\rho)=1-\rho_{1} \rho_{2} \leq 0 \\
& 0 \leq \rho_{1} \leq 10,0 \leq \rho_{2} \leq 10
\end{aligned}
$$

\end{aligned}
$$

## Aerospace Engineering

University of Illinois at Urbana-Champaign

## Evolutionary Algorithms \& Metaheuristics

- Advantages

Straightforward (possibly most-straightforward) to code
Don' t need to know optimal control theory; don' t need possibly difficult analytical differentiation
Requires no initial guess; the initial population is chosen randomly
More likely than other methods to locate the global minimum

- Disadvantages

The problem needs to be parameterized by a (relatively) small number of variables.
The methods depend on a number of user-selectable parameters and it is not a priori clear how these are chosen for a successful or efficient solution.
Likely to need explicit numerical integration of the EOM, which can be time-consuming
The solution will not be as accurate as that of the COV necessary conditions or a DT solution
Constraints need to be included via a penalty function method and this is especially problematic for equality constraints

University of Illinois at Urbana-Champaign

## Example: Max-Radius Orbit Transfer Using Solar Sail Solved Using PSO

Pradipto Ghosh, Ph. D. candidate, Univ. of Illinois 2013
Objective is to determine the solar sail orientation history (the control) in order to transfer the vehicle from a specified initial circular orbit to the largest possible coplanar circular orbit in a fixed time $t_{f}=450$ days

$$
\min _{(\cdot)} J\left[x(\cdot), \quad(\cdot), t_{f}\right]=r\left(t_{f}\right)
$$

Subject to:

$$
\left.\begin{array}{rl}
\dot{r} & =v_{r}, \quad r(0)=1 \\
\cdot & =\frac{v}{r} \\
\dot{v}_{r} & =\frac{v^{2}}{r} \frac{}{r^{2}}+a \frac{\cos ^{3}}{r^{2}} \\
2
\end{array}\right]=\left[\begin{array}{l}
1 \\
v_{r}\left(t_{f}\right)
\end{array}\right]=\left[\begin{array}{l}
0 \\
0
\end{array}\right]
$$

## Example: Max-Radius Orbit Transfer Using Solar Sail Solved Using PSO (2)

The solution for ( t ) was approximated as a sum of 7 quadratic splines.
The order of the spline $p_{s, k}$ is determined according to the "degree-parameter" $m_{s, k}$, which decides the B-spline degree of the sth control in the kth phase in the following fashion:

$$
p_{s, k}=\left\{\begin{array}{ccc}
1 & \text { if } & -2 \leq m_{s, k}<-1 \\
2 & \text { if } & -1 \leq m_{s, k}<0 \\
3 & \text { if } & 0 \leq m_{s, k}<1
\end{array}\right.
$$

The optimal values for the 7 coefficients are found using PSO.

| Parameter | Value |
| :---: | :---: |
| $\alpha_{1}$ | 0.4377 |
| $\alpha_{2}$ | 0.3879 |
| $\alpha_{3}$ | 0.1665 |
| $\alpha_{4}$ | 1.096 |
| $\alpha_{5}$ | 0.9228 |
| $\alpha_{6}$ | 0.7494 |
| $\alpha_{7}$ | 0.6798 |
| $m_{1,1}$ | -0.3364 |

## Example: Max-Radius Orbit Transfer Using Solar Sail Solved Using PSO (3)

The PSO solution is then used as the initial guess for a more-accurate solution using a direct approach (GPM) with NLP solver SNOPT.

The results are compared in these figures.

## Aerospace Engineering

University of Illinois at Urbana-Champaign

## So What is the Best Solution Method?

The answer is definitely problem-dependent, with the most important consideration being (in my judgment) whether the trajectory uses impulsive thrust or low-thrust (electric) propulsion.

The impulsive case, even with planetary flybys, is a parameter optimization problem and can be solved very efficiently using metaheuristics, esp. PSO or GA + PSO.

The low-thrust case is a continuous optimization problem. It must somehow be converted into a parameter optimization problem. The resulting problem is usually orders of magnitude larger than that of the impulsive case.

My work (with many students) in recent years suggests that for trajectories that include low-thrust arcs the best approach is an Metaheuristic Algorithm alone or in combination with a Direct Transcription method.

An example is the immediately preceding solar sail trajectory problem. Note that the PSO solution is very good and the direct solver converges very quickly using the PSO solution as an initial guess!

## Why?

- Both Hamiltonian (COV-based) methods and DT methods require an "initial guess". This is often problematic.

Approximate solution obtained with EA's or heuristics can become the initial guess for a more-accurate COV-based or DT solution.

- Both Hamiltonian methods and DT methods are local.

Heuristic methods are much more likely to find a global minimum.

- For the special case of mission planning problems, a successful solution strategy has been a outer-loop solver/inner-loop solver.

The outer-loop solver chooses the discrete decision parameters and is well suited to a GA.

- As a "bonus", heuristic solutions are much easier to program, e.g. they need no gradient or Jacobian information.

# Lecture 2: Methods for Optimizing Interplanetary Trajectories II / Application to the Problem of NEA Deflection 

Metaheuristic methods for solution of optimal spacecraft trajectory problems: as initial guess for a more precise method or as solution in own right

Need different approaches for "naturally discrete" problems/ continuous-thrust problems
Examples

Proposed methods of asteroid deflection: collision, nuclear explosion, mass drivers, gravity tractor. Advantages and disadvantages.

The objective: maximizing deflection (easy) vs. maximizing displacement from Earth surface (complicated)

Using the state transition matrix to optimize deflection via collision

## Conversion of the Optimal Control Problem for Solution via EA

Using a EA requires that the problem be formulated as a "few parameter" problem in contrast to direct transcription formulations in which there are 100 's to several 1000' s of decision parameters.

All space trajectory problems are continuous, but the associated optimal control problem may be discrete or continuous.
"Naturally Discrete" Cases
Hohmann transfer

Lambert problem transfer
Multiple Gravity Assist (MGA)

Continuous Discrete Cases
Low-thrust transfers

Impulsive + low-thrust transfers
Lyapunov periodic orbits

Example: Hybrid Optimal Control Using Nested Loops - Minimum-Fuel Interplanetary Trajectory with Flybys and Deep Space Maneuvers

Jacob Englander, Ph. D. thesis 2013
The problem is formulated as a hybrid optimal control problem (HOCP).
No a priori information about the solution is provided, only a range of dates is given for departure from Earth and arrival at the target planet.

An outer-loop solver determines the optimal number and sequence of flybys. Each planet in the solar system is given a number (Mercury $=1 \ldots$ Neptune $=8 ; 0$ and 9-15 are null codes). A binary GA determines the prospective sequences; e.g. [ $\left.\begin{array}{lllllll}2 & 3 & 11 & 15 & 5 & 9 & 12\end{array}\right]$ would be an Earth departure followed by flybys at Venus (2), Earth (3) and Jupiter (5) then arrival at the target planet. The null codes allow as many as 7 flybys in the mission.

For each sequence an inner-loop solver, using differential evolution (DE), determines the optimal parameters: dates of all important events, flyby periapse radii; locations and directions of deep space maneuvers.

The optimal cost from the inner-loop solution is returned to the outer-loop GA. The GA then quickly identifies poorly-performing sequences.

Example: Hybrid Optimal Control Using Nested Loops - Minimum-Fuel Interplanetary Trajectory with Flybys and Deep Space Maneuvers (2)

- Allow one deep-space maneuver in each phase, no maneuvers at flyby periapse
- Optimizer Chooses:
- Launch date
- Initial hyperbolic $\boldsymbol{v}_{\infty}$
- For each phase:
- Flight time $T_{i}$
- Burn index $\eta_{i}$
- B-plane insertion angle $\gamma_{i}$

- Flyby periapse distance ratio $R_{p i}$
- In each phase:
- Propagate to burn point via Kepler's method
- Find trajectory from burn point to end point via Lambert's method

Example: Hybrid Optimal Control Using Nested Loops - Minimum-Fuel Interplanetary Trajectory with Flybys and Deep Space Maneuvers (3)

| Option | Value |
| :--- | :--- |
| Arrival type | insertion into orbit about Saturn |
| Semi-major axis of capture orbit about Saturn | 5447500 km |
| Eccentricity of capture orbit about Saturn | 0.998 |
| Launch window open date | $4 / 7 / 1997$ |
| Launch window close date | $1 / 1 / 2000$ |
| Flight time upper bound | 10 years |
| Maximum number of flybys | 8 |

## Conversion of the Continuous Optimal Control Problem for Solution via EA

Problems that are not "naturally discrete", e.g. problems using low-thrust propulsion, must be recast as depending on a small number of decision parameters. There are a number of ways to accomplish this:
i) The thrust magnitude and thrust pointing time histories can be described by polynomials, splines, or Fourier series. The decision parameters are then the coefficients. Optimal solar sail control example.
ii) The arcs during which thrust is applied can be modeled using "shapebased" methods in which a GA chooses the optimal parameters describing the shape. Optimal NEA deflection via impactor example.
iii) The Sims-Flanagan approximation can be used. In this approximation a continuous thrust arc is modeled as a sequence of discrete, small $\quad V^{\prime} s$ Bepi Columbo-like mission
iv) The problem can be formulated using a Hamiltonian method so that the unknowns become unknown initial values of the Lagrange multipliers (costates) of the problem. The states are then found by numerical integration and the control is found using Pontryagin' s principle. Low-thrust circle-circle rendezvous example.

## Multiple Gravity Assist with Low Thrust (MGA-LT)

- Break mission into phases. Each phase starts and ends at a body.
- Sims-Flanagan Transcription
$\diamond$ patch point
$\triangleright$ burn point
- Break phases into time steps
- Insert a small impulse in the center of each time step, with bounded magnitude
- Optimizer Chooses:
- Launch date
- For each phase:
» Initial velocity vector
» Flight time
» Thrust-impulse vector at each time step
» Mass at the end of the phase
» Terminal velocity vector
- Propagate forward and backward from phase endpoints to a "match point"
- Enforce nonlinear state continuity constraints at match point
- Enforce nonlinear velocity magnitude and altitude constraints at flyby

## Example of MGA-LT: "BepiColombo"- like Mission

- Objective is to travel from Earth to Mercury (within a specified range of dates) and maximize payload delivered.
- "Outer-loop" GA chooses number and sequence of planetary flybys
- "Inner-loop" trajectory optimizer first uses monotonic basin hopping (MBH) a heuristic method, to find an approximate solution to be used as an initial guess.
- The problem parameters are the launch date, the time of flight, the magnitude and direction of the departure impulse at Earth, and then all of the Sims-Flanagan parameters that describe each thrust arc (shown in the previous slide).
There are 191 decision variables and 95 constraints
- Then a direct solver using NLP (SNOPT) finds an accurate solution using the MBH solution as its initial guess.

## Example of MGA-LT: "BepiColombo"- like Mission Problem Assumptions

| Option | Value |
| :--- | :--- |
| Arrival type | intercept (match position) with bounded $\mathrm{v}_{\infty}$ |
| Maximum arrival $\mathrm{v}_{\infty}$ | $0.5 \mathrm{~km} / \mathrm{s}$ |
| Launch window open date | $8 / 1 / 2009$ |
| Launch window close date | $4 / 27 / 2012$ |
| Flight time upper bound | 15 years |
| Propulsion type | Fixed Isp and thrust |
| Thrust $(\mathrm{N})$ | 0.34 |
| Isp (s) | 3200 |
| Initial mass $(\mathrm{kg})$ | 1300 |
| Maximum $\Delta \mathrm{v}_{\mathrm{LV}}(\mathrm{km} / \mathrm{s})$ | 1.925 |
| Number of time steps per phase | 10 |
| Maximum number of Flybys | 8 |
| GA Population Size | 100 |
| Inner-Loop run time per sequence | 2 hours |

Objective: maximize mass delivered to Mercury No other information is supplied by the user

\end{array}\right) \\
& =1 / a
\end{aligned}
$$

The unperturbed asteroid' s position on the date of close approach is known.

The asteroid is perturbed by the kinetic impactor, and the state transition matrix is solved analytically to find the difference between the asteroid and its unperturbed reference position on the date of close approach.

The longer the asteroid coasts after receiving impulse from the interceptor, the more it will deviate from its reference course. Thus, in general, the earlier the interceptor hits the asteroid, the farther away the asteroid will pass the Earth.

## Maximization of the Deflection via Nuclear Impulse (1)

The state transition matrix $\left(t, t_{0}\right)$ determines the perturbation in position and velocity:

$$
\left[\begin{array}{c}
\overline{\mathrm{r}} \\
\overline{\mathrm{v}}
\end{array}\right]=\left(\mathrm{t}, \mathrm{t}_{0}\right)\left[\begin{array}{l}
\overline{\mathrm{r}_{0}} \\
\overline{\mathrm{v}_{0}}
\end{array}\right]=\left[\begin{array}{cc}
\widetilde{\mathrm{R}} & \mathrm{R} \\
\widetilde{\mathrm{~V}} & \mathrm{~V}
\end{array}\right]\left[\begin{array}{l}
\overline{\mathrm{r}_{0}} \\
\overline{\mathrm{v}_{0}}
\end{array}\right.
$$

Therefore:

$$
\overline{\mathrm{r}}(\mathrm{t})=\mathrm{R} \quad \overline{\mathrm{v}}_{0}\left(\mathrm{t}_{0}\right)
$$

where $t$ is the time of close approach and $t_{0}$ is the time of interception, where

$$
\begin{aligned}
& {[\mathrm{R}]=\frac{\mathrm{r}_{0}}{}(1-\mathrm{F})\left[\left(\overline{\mathrm{r}}-\overline{\mathrm{r}}_{0}\right) \overline{\mathrm{v}}_{0}^{\mathrm{T}}-\left(\overline{\mathrm{v}}-\overline{\mathrm{v}}_{0}\right) \overline{\mathrm{r}}_{0}^{\mathrm{T}}\right]+\mathrm{C} \overline{\mathrm{v}}_{\bar{v}_{0}^{\mathrm{T}}}+\mathrm{G}[\mathrm{I}]} \\
& \mathrm{F}=1-\frac{\mathrm{r}}{\mathrm{p}}(1-\cos ), \cos =\frac{\overline{\mathrm{r}} \times \overline{\mathrm{r}}_{0}}{\mathrm{r} \mathrm{r}_{0}} \\
& \mathrm{G}=\frac{1}{\sqrt{ }}\left[\frac{\mathrm{r} \mathrm{r}_{0}}{\sqrt{\mathrm{p}}} \sin \right]
\end{aligned}
$$

## Aerospace Engineering

University of Illinois at Urbana-Champaign

## Maximization of the Deflection via Nuclear Impulse (2)

and

$$
\mathrm{C}=\frac{1}{\sqrt{ }}\left[3 \mathrm{U}_{5}-\quad \mathrm{U}_{4}-\sqrt{ }\left(\mathrm{t}-\mathrm{t}_{0}\right) \mathrm{U}_{2}^{-}\right.
$$

where

$$
=\sqrt{\mathrm{a}}\left(\mathrm{E}-\mathrm{E}_{0}\right)
$$

and

$$
\mathrm{U}_{1}(, \quad), \mathrm{U}_{2}(, \quad), \mathrm{U}_{3}(, \quad), \mathrm{U}_{4}(, \quad), \mathrm{U}_{5}(, \quad)
$$

are the "Universal Functions" (cf. Battin' s book), where $=1 / a$

## Maximization of the Deflection via Nuclear Impulse (3)

Want maximum deflection at close approach time $t$, i.e. $\max |\overline{\mathrm{r}}(\mathrm{t})|=\max \left([\mathrm{R}] \overline{\mathrm{v}}_{0}\right)$
This is equivalent to maximizing $\quad \overline{\mathrm{V}}_{0}{ }^{T}[R]^{\mathrm{T}}[\mathrm{R}] \quad \overline{\mathrm{V}}_{0}$
This quadratic form is maximized, for given $\left|\overline{\mathrm{v}}_{0}\right|$, if $\overline{\mathrm{v}}_{0}$ is chosen parallel to the eigenvector of $[R]^{T}[R]$ conjugate to the largest eigenvalue of $[R]^{T}[R]$.

This yields the optimal direction for the perturbing velocity impulse $\overline{\mathrm{V}}_{0}$, (in the space-fixed XYZ basis).

Can then express $\quad \overline{\mathrm{V}}_{0}$ in asteroid-fixed radial, transverse, normal basis as

$$
\overline{\mathrm{V}}_{0 \mathrm{RTN}}=\left[\begin{array}{ccccccccc}
\mathrm{c} & \mathrm{c} & -\operatorname{cis} & \mathrm{s} & \mathrm{c} & \mathrm{~s} & +\operatorname{cic} & \mathrm{s} & \operatorname{sis} \\
-\mathrm{s} & \mathrm{c} & -\operatorname{cis} & \mathrm{c} & -\mathrm{s} & \mathrm{~s} & +\operatorname{cic} & \mathrm{c} & \operatorname{sic} \\
& & \operatorname{sis} & & & & -\operatorname{sic} & & \mathrm{ci}
\end{array}\right] \overline{\mathrm{V}}_{0 \mathrm{XYZ}}
$$

## Maximization of the Miss Distance from Earth Surface (1)

As shown in a previous slide, maximizing deflection magnitude is straightforward, using the system state transition matrix.

However the real objective is to maximize the miss distance altitude, which is the same as maximizing the miss distance radius (from the center of the Earth).

This is accomplished by maximizing the perigee radius of the asteroid's hyperbolic flyby.

## Maximization of the Miss Distance from Earth Surface (2)

It is first necessary to determine the heliocentric position and velocity at entry onto the Earth arrival hyperbola:

$$
\left[\begin{array}{c}
\vec{r}\left(t_{f}\right) \\
\vec{v}\left(t_{f}\right)
\end{array}\right]=\Phi\left(t_{f}, t_{\text {inererece }}\right)\left[\begin{array}{c}
0 \\
\delta \vec{v}_{0}
\end{array}\right]+\left[\begin{array}{l}
\vec{r}_{\text {referene }}\left(t_{f}\right) \\
\vec{v}_{\text {referenere }}\left(t_{f}\right)
\end{array}\right]
$$

Then, the miss distance from the Earth's center may be found as:

$$
r_{m i s s}=a_{f / b}\left(\begin{array}{ll}
1 & e_{f / b}
\end{array}\right)
$$

where

$$
a_{f / b}=\quad \text { earth } / v^{2}
$$

$v_{\infty}$ is the hyperbolic approach velocity given by

$$
\left.\left.v_{\infty}=\| v_{\text {defecteced }} \mid t_{f}\right)-v_{\text {earth }} \mid t_{f}\right) \|
$$

and $e_{f / b}$ is the eccentricity of the hyperbolic trajectory given by

$$
\left.e_{f l b}=\csc (/ 2) \quad \text { where } \quad \delta=2 \tan ^{-1} \left\lvert\, \frac{\mu_{\text {earth }}}{\left\|\vec{r}_{\text {deflected }}\left(t_{f}\right)-\vec{r}_{\text {earth }}\left(t_{f}\right)\right\| \cdot v_{\infty}^{2}}\right.\right)
$$

Lecture 3: Asteroid Deflection/ Characterization by Sample Return

Optimizing asteroid deflection (magnitude) via nuclear explosion using a low-thrust spacecraft

Optimizing asteroid deflection (from Earth surface) via collision using a low-thrust spacecraft

Optimizing a manned reconnaissance/sample return mission to an asteroid
Examples and results

## Example: Deflection of PHA Using Nuclear Impulse and a Low-Thrust Spacecraft

- Simulation assumes use of current technology
- Low-thrust propulsion is used because of its great efficiency
- It is assumed that the nuclear explosion can be exploded at the moment of close approach, i.e. rendezvous is not required
- It will be shown that use of low-thrust electric propulsion yields a dramatic increase in payload delivered to the asteroid
- The problem is formulated using the Gauss variational equations in (singularity-- free) equinoctial elements:

$$
a, P_{1}=e \sin \quad, P_{2}=e \cos , Q_{1}=\tan \frac{i}{2} \sin , Q_{2}=\tan \frac{i}{2} \cos , L
$$

- The optimal control problem is constructed using a direct transcription method (collocation with $5^{\text {th }}$ degree Gauss-Lobatto defects) and solved using a NLP problem solver (NPSOL).
- The control variables are the in-plane (azimuthal) thrust pointing angle and the out-of plane thrust pointing angle. The optimizer may also choose the direction of the hyperbolic departure from Earth.

## Aerospace Engineering

## "Independence" of Trajectory and Deflection

In principle
The solution to the "complete" problem involves finding optimal values (or time histories) of all free parameters, from Earth departure to interception, e.g. optimal departure point in Earth orbit, departure direction, optimal thrust pointing history, arrival date, direction of application of impulse, etc.

The locus of points where a deflection impulse can be applied is the asteroid orbit!

So best direction of application of impulse and resulting maximum deflection can be found independently of the interception trajectory!

## However

It is still necessary to intercept the asteroid optimally - an optimal low-thrust trajectory is found to each candidate interception point.

## Initial Condition Constraints

The initial condition constraints yield the following 6 scalar equations:

$$
\begin{gathered}
\mathrm{a}_{\mathrm{E}} \cos \mathrm{E}-\frac{\mathrm{r}\left[\cos \mathrm{~L}+\left(\mathrm{Q}_{2}^{2}-\mathrm{Q}_{1}^{2}\right) \cos \mathrm{L}+2 \mathrm{Q}_{1} \mathrm{Q}_{2} \sin \mathrm{~L}\right]}{1+\mathrm{Q}_{2}^{2}+\mathrm{Q}_{1}^{2}}=0 \\
\mathrm{a}_{\mathrm{E}} \sin \mathrm{E}-\frac{\mathrm{r}\left[\sin \mathrm{~L}-\left(\mathrm{Q}_{2}^{2}-\mathrm{Q}_{1}^{2}\right) \sin \mathrm{L}+2 \mathrm{Q}_{1} \mathrm{Q}_{2} \cos \mathrm{~L}\right]}{1+\mathrm{Q}_{2}^{2}+\mathrm{Q}_{1}^{2}}=0 \\
\frac{2 \mathrm{r}\left[\mathrm{Q}_{2} \sin \mathrm{~L}-\mathrm{Q}_{1} \cos \mathrm{~L}\right]}{1+\mathrm{Q}_{2}^{2}+\mathrm{Q}_{1}^{2}}=0
\end{gathered}
$$

$$
\begin{gathered}
\frac{\sqrt{\mathrm{p}}\left[\sin \mathrm{~L}+\left(\mathrm{Q}_{2}^{2}-\mathrm{Q}_{1}^{2}\right) \sin \mathrm{L}-2 \mathrm{Q}_{1} \mathrm{Q}_{2} \cos \mathrm{~L}+\mathrm{P}_{1}-2 \mathrm{P}_{2} \mathrm{Q}_{1} \mathrm{Q}_{2}+\left(\mathrm{Q}_{2}^{2}-\mathrm{Q}_{1}^{2}\right) \mathrm{P}_{1}\right]}{1+\mathrm{Q}_{2}^{2}+\mathrm{Q}_{1}^{2}} \\
\frac{\sqrt{/ \mathrm{p}}\left[-\cos \mathrm{L}+\left(\mathrm{Q}_{2}^{2}-\mathrm{Q}_{1}^{2}\right) \cos \mathrm{L}+2 \mathrm{Q}_{1} \mathrm{Q}_{2} \cos \mathrm{~L}-\mathrm{P}_{2}+2 \mathrm{P}_{1} \mathrm{Q}_{1} \mathrm{Q}_{2}+\left(\mathrm{Q}_{2}^{2}-\mathrm{Q}_{1}^{2}\right) \mathrm{P}_{2}\right]}{1+\mathrm{Q}_{2}^{2}+\mathrm{Q}_{1}^{2}} \\
+\mathrm{v}_{\mathrm{E}} \cos \mathrm{E}+\mathrm{v} / \mathrm{E} \cos 0 \cos \left(0^{-}-\mathrm{E}\right)=0
\end{gathered}
$$

$$
\frac{2 \sqrt{\mathrm{p}}\left[\mathrm{Q}_{2} \cos \mathrm{~L}+\mathrm{Q}_{1} \sin \mathrm{~L}-\mathrm{P}_{2}+\mathrm{P}_{1} \mathrm{Q}_{1}+\mathrm{Q}_{2} \mathrm{P}_{2}\right]}{1+\mathrm{Q}_{2}^{2}+\mathrm{Q}_{1}^{2}}-\mathrm{v} / \mathrm{E} \sin { }_{0}=0
$$

where all unsubscripted variables and elements refer to the orbit of the interceptor spacecraft, $E$ is the true longitude of the Earth, $\mathrm{v}_{\mathrm{E}}$ is
the circular velocity of the Earth and all quantities are evaluated at $\mathrm{t}=0$.

## Aerospace Engineering

$\underline{\underline{W}}$

## Terminal Constraints (Interception)

The terminal constraint yields the following 3 scalar equations:

$$
\begin{align*}
& r_{A}\left[\cos \quad A \cos \quad A-\cos i_{A} \sin \quad A_{A} \sin \quad A\right]-\frac{r\left[\cos L+\left(Q_{2}^{2}-Q_{1}^{2}\right) \cos L+2 Q_{1} Q_{2} \sin L\right]}{1+Q_{2}^{2}+Q_{1}^{2}}=0 \\
& r_{A}\left[\cos \quad{ }_{A} \cos \quad A^{-}-\cos i_{A} \sin \quad A_{A} \sin \quad A\right]-\frac{r\left[\sin L-\left(Q_{2}^{2}-Q_{1}^{2}\right) \sin L+2 Q_{1} Q_{2} \cos L\right]}{1+Q_{2}^{2}+Q_{1}^{2}}=0 \\
& \mathrm{r}_{\mathrm{A}} \sin \mathrm{i}_{\mathrm{A}} \sin \mathrm{~A}^{-2 r\left[\mathrm{Q}_{2} \sin \mathrm{~L}-\mathrm{Q}_{1} \cos \mathrm{~L}\right]} 11+\mathrm{Q}_{2}^{2}+\mathrm{Q}_{1}^{2} \quad=0 \tag{12}
\end{align*}
$$

where all unsubscripted variables refer to the orbit of the interceptor spacecraft and all quantities are evaluated at tFinal.

## Target is Asteroid 1991RB

Orbit of Asteroid 1991RB:

$$
\begin{gathered}
\begin{array}{c}
\mathrm{a}=1.4524 \mathrm{AU} \\
\mathrm{e}=.4846 \\
\mathrm{i}=19.578^{\circ} \\
=359.738^{\circ} \\
=68.703^{\circ} \\
\mathrm{M}=225.871^{\circ} \\
\text { At epoch } 3 / 18 / 1998
\end{array} . \begin{array}{l} 
\\
\hline
\end{array}{ }^{\circ} \mathrm{C}
\end{gathered}
$$

Asteroid 1991RB had a close approach to Earth of .0401 AU (= 15.62 Lunar Distances) on 9/18/1998.

## A Sample Trajectory

Example trajectory: launch 6 months before close approach; interception 38 days before close approach

## Advantage of Interception Using Low-Thrust (1)

Compare propellant and structural mass fractions required to intercept asteroid, in same time-of-flight, for impulsive case vs. using low-thrust electric propulsion.
Uses results from a typical case.

Problem: Find $\quad V$ required to take spacecraft from given $\bar{r}_{1}$ to $\bar{r}_{2}$ in flight time $\mathrm{t}_{\mathrm{F}}=2.5096$ units $=145.89$ days.
Method: This is a "Lambert" problem. Solve Lambert's stime-of-flight equation for the semimajor axis of the elliptical section connecting the given points in the specified time.

Result: Trajectory has $\mathrm{a}=1.31973 \mathrm{AU}$; can solve for absolute velocity at departure yielding $\overline{\mathrm{v}_{1}}=[.0931,-1.040,-.3883$

Velocity at escape from Earth is $\overline{\mathrm{v}}_{\text {Earth }}+\overline{\mathrm{v}}=\lfloor-.0241,-1.008,-0.020\rfloor$
Difference is required $\overline{\mathrm{V}}=[.069,-.032,-.368$

## Advantage of Interception Using Low-Thrust (2)

Then

$$
\begin{aligned}
\mathrm{V} & =.414 \text { in normalized units } \\
& =12.32 \mathrm{~km} / \mathrm{sec}
\end{aligned}
$$

For a optimal two-stage chemical rocket, with (good) Isp $=375 \mathrm{sec}$, and structural coefficient of 0.12 for each stage:
1 st stage mass $=70.53 \times$ payload mass
2 nd stage mass $=7.91 \times$ payload mass
thus, propellant required is $88 \%$ of rocket mass or $69.0 \times$ payload mass.
Payload mass is approximately $1-3 \%$ of mass at departure!
For the low-thrust (electric) motor, with Isp $=4000 \mathrm{sec}$, of case N, final thrust acceleration is .191, initial thrust accel. is $.14=.83 \mathrm{mN} / \mathrm{kg}$ thus,

$$
\frac{\mathrm{m}_{0}}{\mathrm{~m}_{0}-\mathrm{m}_{\text {fuel }}}=\frac{\text { final acceleration }}{\text { initial acceleration }}=\frac{.191}{.140}=1.364
$$

i.e., fuel mass is $27 \%$ of payload mass (assuming structural coefficient $=0.1$ ) Present ion propulsion technology requires 1.4 kg propulsion hardware $/ \mathrm{mN}$ thrust. Near-term improvement expected to $0.7 \mathrm{~kg} / \mathrm{mN}$. Thus total propulsion system mass is $.83 \mathrm{mN}(.7 \mathrm{~kg} / \mathrm{mN})+.27 \mathrm{~kg}$ fuel +.03 kg tank $=.88 \mathrm{~kg} / \mathrm{kg}$. So payload mass is

## Example: Deflection of PHA Using Impact and a Low-Thrust Spacecraft

## J. Englander M.S. thesis, Univ. of Illinois (2008)

Objective is to find a low-thrust trajectory for a spacecraft whose impact is to maximize the subsequent deflection distance when the asteroid approaches the Earth.

Launch vehicle upper stage applies a departure impulse in low Earth orbit. The amount of fuel used for this purpose (at lower $I_{\text {sp }}$ ) is chosen by the optimizer. Then the spacecraft engages a low thrust electric motor and travels to the asteroid.

The time histories of thrust magnitude and steering angle (the two continuous controls) must be found to optimally guide the spacecraft to the asteroid.

An approximate optimal (and feasible) solution is found with a GA using a "shapebased" representation of the trajectory. The GA has 9 free parameters: it uses 50 generations with a population $\mathrm{n}=50$.

The solution from the GA is then used to initialize a much more accurate solution using a direct transcription method (Runge-Kutta parallel shooting) and a NLP problem solver (SNOPT)

## The Asteroid

- Hypothetical asteroid based on 99942 Apophis impacts Earth on April 13 ${ }^{\text {th }}, 2029$ (Apophis will miss Earth by 32000 km )
- Same mass as 99942 Apophis ( $\left.\sim 4.6 \times 10^{10} \mathrm{~kg}\right)$

Orbit elements, April 13 ${ }^{\text {th }}, 2021$ (very slightly modified to yield impact rather than a 32000 km miss):
$\mathrm{a}=0.9214 \mathrm{AU}$
$\mathrm{e}=0.1957$
$\mathrm{i}=3.42^{\circ}$
$\omega=126.62^{\circ}$
$\Omega=203.79^{\circ}$
$\mathrm{f}=231.54^{\circ}$

## Assumptions

- Spacecraft is launched on Delta IV Heavy
- Delta IV heavy can place 25000 kg in 300 km altitude LEO parking orbit, including spacecraft, fuel, and launch vehicle upper stage dry mass
- Upper stage engine has Isp $=462 \mathrm{~s}(\mathrm{RL}-10)$
- Low thrust electric motor (same as Dawn, DS-1) has Isp $=3100 \mathrm{~s}$, thrust $=90 \mathrm{mN}$
- We mount two of these engines, for a total thrust of 180 mN
- Launch window opens April 13 ${ }^{\text {th }}, 2021$ - 8 years before the 2029 impact

## The Optimal Trajectory Parameters Found via GA

GA parameters and their bounds

| Parameter | Lower bound | Upper bound |
| :---: | :---: | :---: |
| Launch date after epoch (TU) | 0.001 | 8.40 |
| Flight time (TU) | 0.001 | 40.0 |
| Number of revolutions | 0.0 | 1.0 |
| Arrival velocity magnitude (AU/TU) | 0.001 | 5.0 |
| In-plane arrival flight path angle (radians) | $-\pi / 4$ | $\pi / 4$ |
| Out-of-plane arrival flight path angle (radians) | $-\pi / 4$ | $\pi / 4$ |
| Initial impulse inplane pointing angle (radians) | $-\pi$ | $\pi$ |
| Initial impulse out-ofplane pointing angle (radians) | $-\pi$ | $\pi$ |
| Propellant used for initial impulse (kg) | 12985 | 19000 |

Optimal values of the GA parameters

| Parameter | Optimal <br> value |
| :--- | :---: |
| Launch date after epoch (TU) | 4.8705 |
| Flight time (TU) | 10.2041 |
| Number of revolutions | 0.1267 |
| Arrival velocity magnitude | 1.2180 |
| (AU/TU) | 0.1916 |
| In-plane arrival flight path <br> angle (radians) <br> Out-of-plane arrival flight <br> path angle (radians) <br> Initial impulse in-plane <br> pointing angle (radians) <br> Initial impulse out-of-plane <br> pointing angle (radians) <br> Propellant used for initial <br> impulse (kg) | 0.0130 |

## Shape-Based Approximation to Trajectory

The 9 GA parameters determine (among other things) $\left[\begin{array}{lll}r_{1}, & 1, \dot{r}_{1}, & { }_{1}\end{array}\right]$ and $\left[\begin{array}{lll}r_{2}, & \dot{r}_{2}, & \dot{L}_{2}\end{array}\right]$
Then the path is approximated parametrically as an inverse $6^{\text {th }}$ degree polynomial:

$$
r(\theta)=\frac{1}{a+b \theta+c \theta^{2}+d \theta^{3}+e \theta^{4}+f \theta^{5}+g \theta^{6}}
$$

The seven coefficients $a-g$ may be solved for using the 9 GA parameters directly and indirectly, e.g. it is obvious that $r_{1}=1 / a$.

The thrust magnitude and flight path angle may be found a posteriori as

$$
\begin{aligned}
& \text { in }=\frac{6 d+24 e+60 f^{2}+120 g^{3}(\tan ) / r}{2 r^{3} \cos } \frac{\left[(1 / r)+2 c+6 d+12 e^{2}+20 f^{3}+30 g^{4}\right]^{2}}{\tan }=r \ngtr\left(b+2 c+3 d^{2}+4 e^{3}+5 f^{4}+6 g^{5}\right)
\end{aligned}
$$

For the 3D case need to also parameterize the vertical motion using:

$$
z()=a_{z}+b_{z}+c_{z}^{4}+d_{z}^{5}
$$

## GA Convergence History

GA objective function is scaled by parameter $h$ in order to penalize trajectories that need a thrust acceleration larger than what the vehicle can actually provide, i.e.

| Generation Best J (km) |  |
| :--- | :--- |
| 1 | -58.1 |
| 2 | -94.9 |
| 3 | -94.9 |
| 4 | -333.5 |
| 5 | -609.4 |
| 7 | -859.6 |
| 10 | -1257 |
| 12 | -1318 |
| 14 | -1483 |
| 18 | -1729 |
| 21 | -2408 |
| 26 | -2519 |
| 27 | -2959 |
| 28 | -3387 |
| 29 | -4048 |
| 37 | -4496 |
| 38 | -4754 |
| 39 | -4943 |
| 40 | -5162 |
| 41 | -5178 |
| 47 | -5358 |
| 50 | -5358 |

equiv. to $30,967 \mathrm{~km}$

## Guess Trajectory (from GA) and Final Trajectory

Initial guess of 3D trajectory from the GA

Converged NLP solution using this initial guess

## Aerospace Engineering

University of Illinois at Urbana-Champaign

## Converged Solution From NLP Solver

- Departure: 13 April 2021
$V=5.36 \mathrm{~km} / \mathrm{sec}$
Consumes 15613 kg of propellant
- Powered flight: Consumes 696 kg of propellant
- Interception: 2 March 2023

Impact changes velocity of Apophis by $2.7 \mathrm{~mm} / \mathrm{sec}$

- Deflection: 17041 km

## Optimal Control Time History

University of Illinois at Urbana-Champaign

## Example: Manned Asteroid Sample Return Mission with Time Constraint (1)

Aishwarya Stanley, M.S. thesis 2013
Objective is to minimize $\Delta \mathrm{V}$ for sample return mission with 8-25 day stay at asteroid and max 365 day total trip time.

NEA catalog searched for candidates satisfying the following criteria:

1. Allow departure dates between 2025 and 2035
2. Are at least 30 m in diameter
3. Allow 365 day round trip missions
and are not limited by the following considerations:
4. Uncertain orbit and/or limited Earth-based observation
5. Few departure opportunities
6. Likely too small based on estimated albedo (albedo assumed to be between 0.05 and 0.25 )

Lambert's method is used to find the $\Delta V$ 's required for Earth departure, asteroid interception, asteroid departure, and Earth arrival.

The only free parameters are the four dates of those events.

NASA researchers had used a brute force approach, generating tens of thousands (hundreds of thousands?) of missions for each asteroid for various values of each of those 4 dates.

Our research used PSO to determine the optimal mission.

A penalty function is used to limit total flight time to 365 days.
